

# Protein Synthesis

# 2.7 Gene Expression

**Fibrous proteins:** tough rope-like bundles = collagen + keratin  
 ↳ tendons, ligaments, muscles, bone.

**Globular proteins:** irregularly folded into 3-D shape e.g. enzymes and hormones.  
 ↳ information to make these = stored in genes.

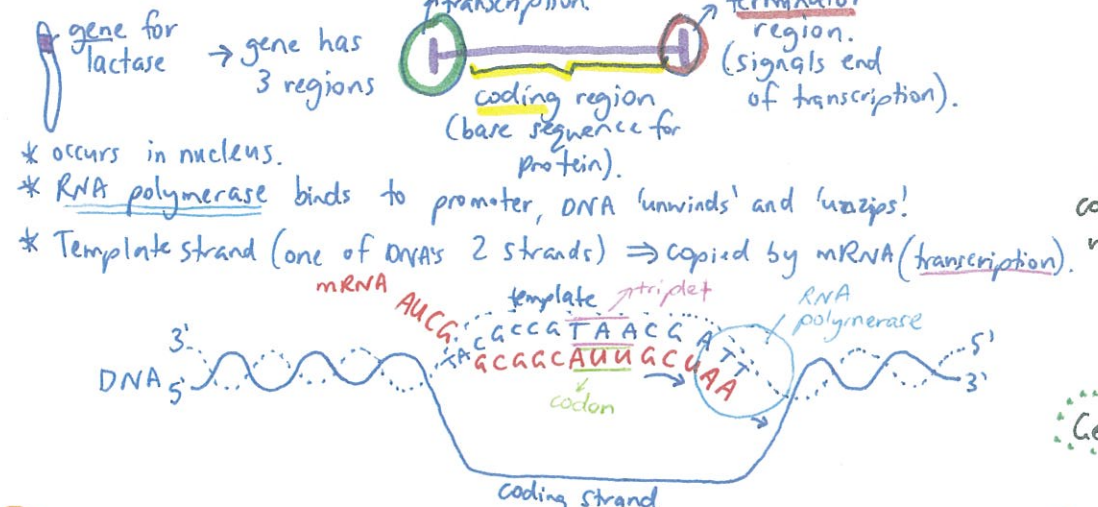

length of DNA which codes for a polypeptide  
 ↳ mutation? → mis-sense → non-sense  
 ↳ same-sense (silent)

**Proteins:** are polymers, made up of amino acids (monomers).

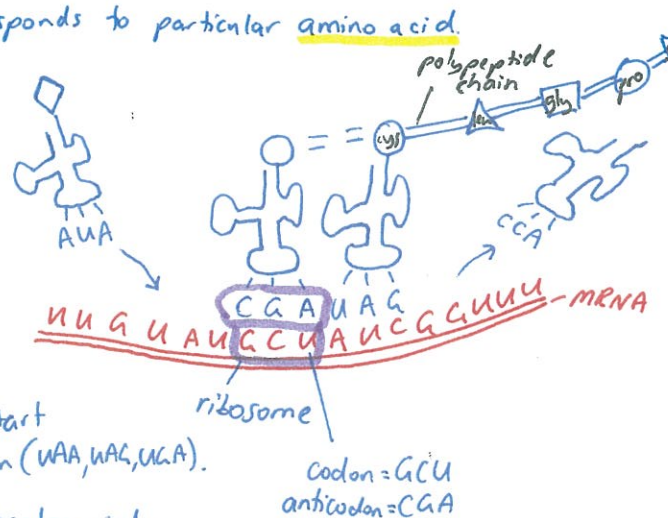

**Enzymes:** active site = most important part.  
 ↳ denatured - pH (H-bonds) - temp.  
 ↳ mutation? → knock-on effect if in metabolic pathway.

## TRANSCRIPTION:

## TRANSLATION:

\* occurs in cytoplasm.  
 \* mRNA leaves nucleus, travels to ribosomes.  
 \* ribosomes 'read' coded message on mRNA, 3 bases at a time (codon).  
 \* Each codon (triplet in DNA) corresponds to particular amino acid.

\* ribosomes move along mRNA from start codon (AUG) until it reaches a stop codon (UAA, UAG, UGA).  
 ↳ when tRNA anticodon matches complementary codon, amino acid attached to that tRNA is bonded to polypeptide chain.  
 ↳ Polypeptide chain folds, coils, to form protein.

**Redundancy:** 64 possible triplet combinations from 3 bases (triplet) and 4 possible bases (A, T, G, C).  
 \* genetic code is redundant as many amino acids can be specified or by more than one codon. e.g. Leu has 6x possible codons.  
 Advantage = if mutation, there is a chance it still codes for same amino acid. ↳ can still function same.

**Mutagen:** environmental factor that changes genetic material (DNA) → increasing rate of mutations (remember: without mutagens, mutations will still occur spontaneously).  
 ↳ chemical compounds which break DNA strands.  
 ↳ carcinogens → viruses (Hep. B).  
 ↳ (X-rays, UV) ionising radiation.

## Mutations:

Gene (change base sequence).  
 ↳ Chromosome (changes whole genes or chromosomes).  
 ↳ (not in this topic)

- 1. BASE SUBSTITUTION (a.k.a. BASE REPLACEMENT)
- 2. BASE INSERTION
- 3. BASE DELETION

\* Any change in function of protein produces a change in phenotype of individual.

↳ nonsense? ↳ mis-sense? ↳ can be silent/same sense (code is redundant).  
 ↳ may not alter function of protein e.g. if not on enzyme active site.  
 ↳ reading frame shift error. ↳ almost always damaging unless occurring at end of gene.

## Metabolic Pathways:

**Metabolism:** chemical processes that take place within cells.  
 ↳ They are all linked into networks through shared substrates e.g. phenylalanine (amino acid) is needed for melanin (via series of steps) and thyroxine (via series of steps).  
 ↳ what happens if mutation in enzyme part of a pathway? ↳ think about possible build-up of intermediates and loss of final products.  
 ↳ Product of one enzyme-controlled reaction becomes substrate for the next.  
 \* negative feedback: sufficient end-product = pathway stops.

- 1 Protein Synthesis ✓
  - 2 Mutations ✓
  - 3 Metabolic Pathways ✓
  - 4 Environmental effects on Phenotype ✓
  - 5 Enzymes ✓

## Environmental Effects on Phenotype:

genotype + environment → phenotype  
 \* these changes are not heritable.  
 e.g. (3 genes) skin colour and sun exposure → genotype unchanged but phenotype modified.  
 • nutrient availability  
 • temperature  
 • altitude  
 • latitude  
 • acidity levels  
 • weather (wind) → e.g. slanting trees  
 \* TSD (temperature-dependent sex determination) i.e. in reptiles... ↓C = males in turtles. ↑C = females in tuatara and lizards.  
 \* Colour pointina: i.e. in rats. mutation → heat sensitive enzyme → high temp = no melanin (enzyme denatured) → only coloured on ears.

I wish I was Adenine...  
 ... Then I could get paired with U.

Did you just mutate into a stop codon?... Because you're talking non-sense
